Setting Up a Domain Controller

Here's a step-by-step guide to setting up a Domain Controller in Windows Server:

1. **Install Windows Server:** Install the Windows Server operating system on the server that will become the Domain Controller.

2. **Install Active Directory Domain Services (AD DS):**

- Open **Server Manager**.
- Click on **Manage** > **Add Roles and Features**.
- In the **Add Roles and Features Wizard**, select **Role-based or feature-based installation**.
- Select the server where AD DS will be installed.
- In the **Roles** section, check **Active Directory Domain Services**.
- Click **Add Features** when prompted.
- Proceed through the wizard and click **Install**.

3. **Promote the Server to a Domain Controller:**

- After AD DS is installed, there will be a notification flag in Server Manager. Click on it and select **Promote this server to a domain controller**.
- In the **Deployment Configuration** wizard, choose:
- **Add a new forest** if this is the first DC in a new environment.
- **Add a new domain to an existing forest** if there's already a DC and you're adding another domain.
- **Add a domain controller to an existing domain** if there's already a domain and you're adding another DC for redundancy or load balancing.
- Enter the **Root domain name** (e.g., **ncit.edu.np**).
- Specify **Domain Controller Options**, including the Directory Services Restore Mode (DSRM) password.
- Proceed through the wizard, configuring DNS, additional options, and paths as necessary.
- Review the selections and install. The server will restart.

4. **Configure DNS (if applicable):**

- If DNS is installed as part of the AD DS role, ensure it’s properly configured to resolve the domain names.

5. **Create Users and Organizational Units:**

- Open **Active Directory Users and Computers**.
- Create Organizational Units (OUs) to organize users and resources.
- Create user accounts and assign them to OUs as needed.
